“Imaginary-time theory for triple-alpha reaction rate”

Triple-alpha process

Total angular momentum 0

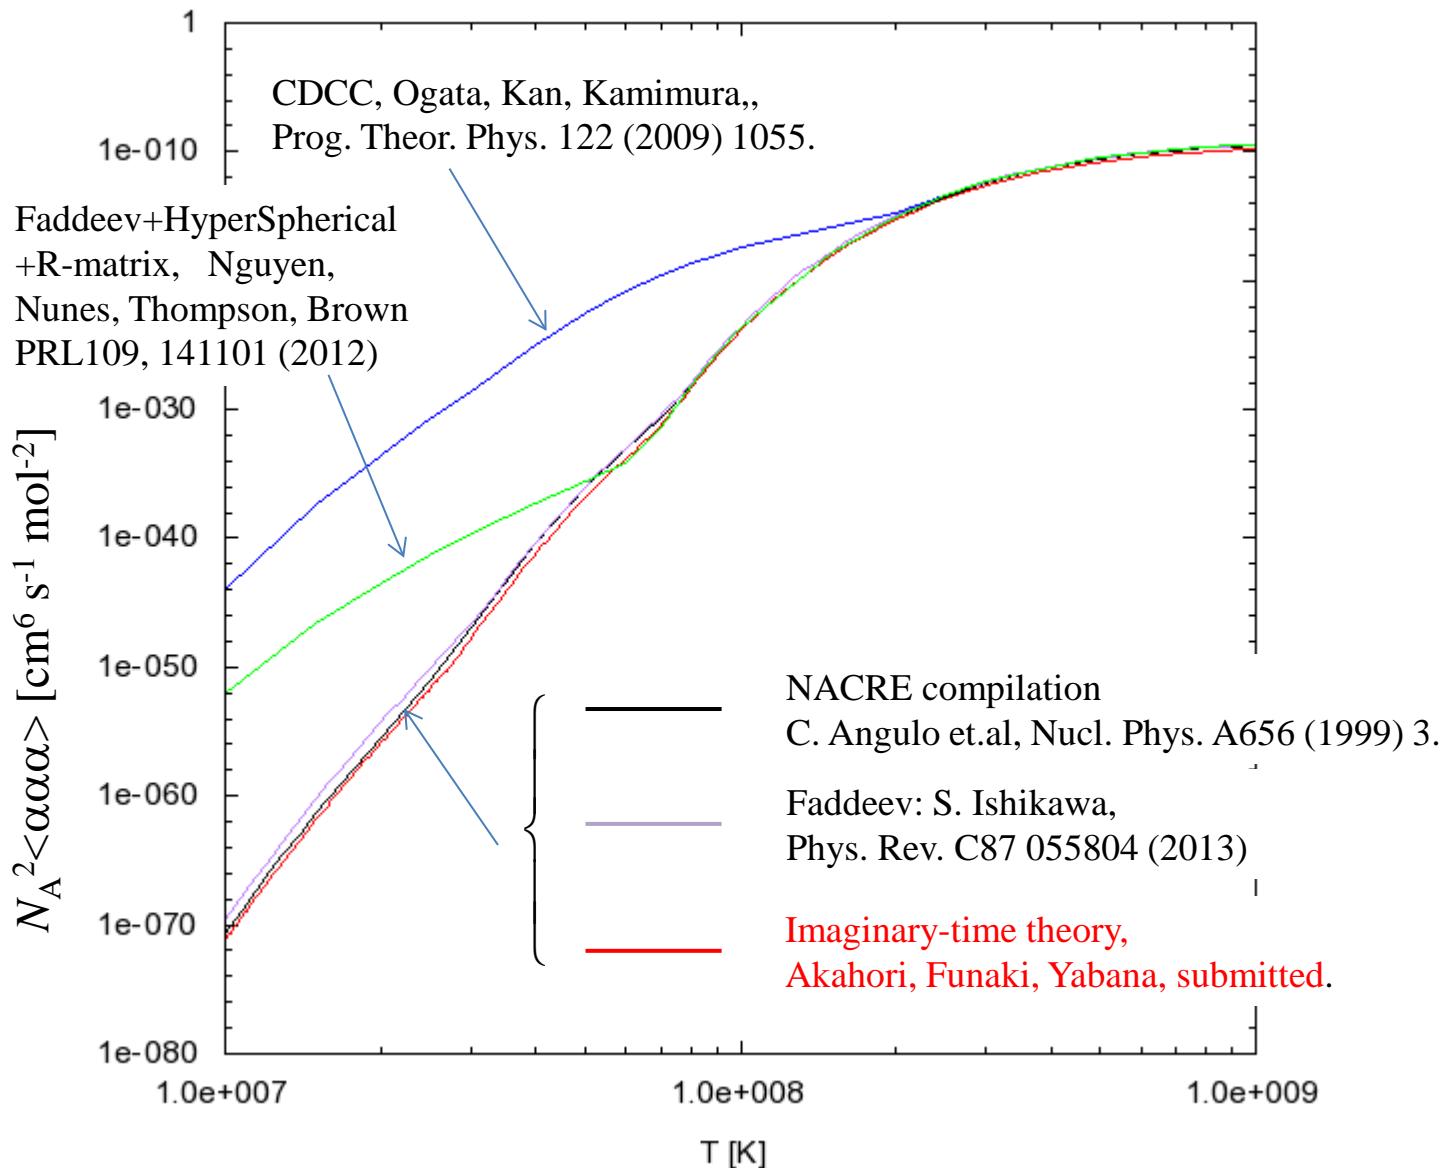

1953 F. Hoyle predicted resonance state in ^{12}C and later confirmed experimentally.

1985 K. Nomoto proposed an empirical formula applicable at low temperature, assuming sequential $\alpha\alpha$ and $\alpha^8\text{Be}$ reactions. (adopted in NACRE)

$$\langle \alpha\alpha\alpha \rangle = 3 \int_0^\infty \frac{\hbar}{\Gamma_\alpha(\text{Be}, E_{\alpha\alpha})} \frac{d\langle \alpha\alpha \rangle(E_{\alpha\alpha})}{dE_{\alpha\alpha}} \langle \alpha\text{Be}(E_{\alpha\alpha}) \rangle dE_{\alpha\alpha}$$

2009- Serious quantum-mechanical calculations of triple-alpha reaction rate started.
At present, controversial among theories.

Calculated rates deviates among theories at low temperature 10^{26} order of magnitude difference at 10^7 K

Difficulties and theoretical challenges of triple-alpha reaction

- Experimental measurement is very difficult.
- Lack of exact theory for scattering of three charged particles,
(we do not know “Coulomb wave function” for 3-charged particles).
- The reaction rate changes 10^{60} in magnitude between $10^7 - 10^9$ K
due to quantum tunneling nature of the process..

Develop a new theory: Imaginary-time theory

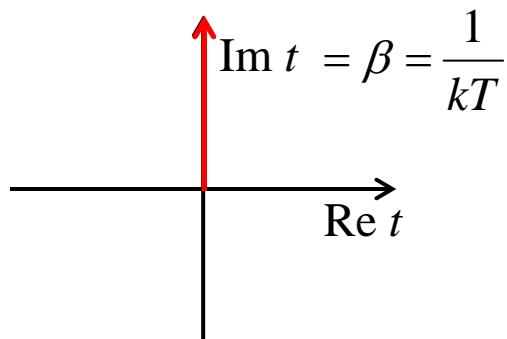

Contents

2. Numerical results
3. Derive empirical formula from the imaginary-time theory
4. Difficulties of coupled-channels approach

What is the “imaginary-time” ?

Identifying inverse temperature
with imaginary-time,

A standard procedure in
thermal quantum
many-body theory

Difference from ordinary approach

Standard procedure

Cross section as a function of energy, $\sigma(E)$.

Thermal average to obtain reaction rate, $\langle v\sigma \rangle$.

Imaginary-time theory

K.Yabana and Y.Funaki. PRC85,055803(2012)

We directly calculate reaction rate, $\langle v\sigma \rangle$,
without solving any scattering problem.

Imaginary-time theory: Derivation

Radiative capture cross section

$$v\sigma_{fi} \propto \left(\frac{E_{\vec{k}} - E_f}{\hbar c}\right)^{2\lambda+1} \left| \int d\vec{r} \phi_f^*(\vec{r}) M_{\lambda\mu} \phi_{\vec{k}}(\vec{r}) \right|^2$$

$M_{\lambda\mu} = \sum_{i \in p} r_i^\lambda Y_{\lambda\mu}(\hat{r}_i)$

λ photon multipolarity

Final: bound state Initial: scattering state

$$\int d\vec{r} |\phi_f(\vec{r})|^2 = 1$$

$$\phi_{\vec{k}}(\vec{r}) \rightarrow e^{i\vec{k}\vec{r}} + f(\hat{r}) \frac{e^{ikr}}{r} \quad (2\text{-body})$$

Reaction rate at temperature at $\beta = 1/k_B T$

$$\langle v\sigma \rangle \propto \int d\vec{k} e^{-\beta E_{\vec{k}}} v\sigma_{fi}$$

$$\langle v\sigma_{fi} \rangle \propto \int d\vec{k} e^{-\beta E_{\vec{k}}} \left(\frac{E_{\vec{k}} - E_f}{\hbar c} \right)^{2\lambda+1} \langle \phi_f | M_{\lambda\mu} | \phi_{\vec{k}} \rangle \langle \phi_{\vec{k}} | M_{\lambda\mu}^+ | \phi_f \rangle$$

↓ Eliminate scattering state using spectral representation

$$f(\hat{H}) = \sum_n f(E_n) \langle \phi_n | \phi_n \rangle + \int d\vec{k} f(E_{\vec{k}}) \langle \phi_{\vec{k}} | \phi_{\vec{k}} \rangle$$

$$\langle v\sigma_{fi} \rangle \propto \langle \phi_f | M_{\lambda\mu} e^{-\beta \hat{H}} \left(\frac{\hat{H} - E_f}{\hbar c} \right)^{2\lambda+1} \hat{P} M_{\lambda\mu}^+ | \phi_f \rangle$$

$$\hat{P} = 1 - \sum_n |\phi_n\rangle\langle\phi_n|$$

Final expression does not include any scattering states.

Imaginary-time theory : Calculation in practice

$$\langle v\sigma_{fi} \rangle \propto \langle \phi_f | M_{\lambda\mu} e^{-\beta\hat{H}} \left(\frac{\hat{H} - E_f}{\hbar c} \right)^{2\lambda+1} \hat{P} M_{\lambda\mu}^+ | \phi_f \rangle$$

Start with 2^+ state of ^{12}C
 (wave function after radiative capture)
 multiplied with E2 operator

$$\psi(\beta = 0) = M_{\lambda=2,\mu}^+ \phi_f(^{12}\text{C}, 2^+)$$

Evolve along imaginary-time axis

$$-\frac{\partial}{\partial \beta} \psi(\beta) = H \psi(\beta)$$

Reaction rate as expectation value

$$\langle v\sigma \rangle \propto \left\langle \psi\left(\frac{\beta}{2}\right) \left| \left(\frac{\hat{H} - E_f}{\hbar c} \right)^{2\lambda+1} \right| \psi\left(\frac{\beta}{2}\right) \right\rangle$$

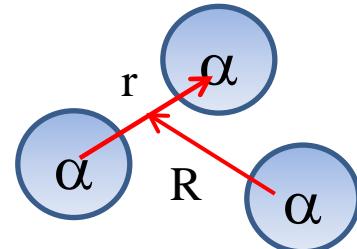

Hamiltonian of 3 alpha particles

$$H = T + V_{12} + V_{23} + V_{31} + V_{123}$$

$V_{\alpha\alpha}$ to reproduce ^8Be resonance energy

$V_{\alpha\alpha\alpha}$ to reproduce resonance energy of
 Hoyle state (0_2^+ of ^{12}C)

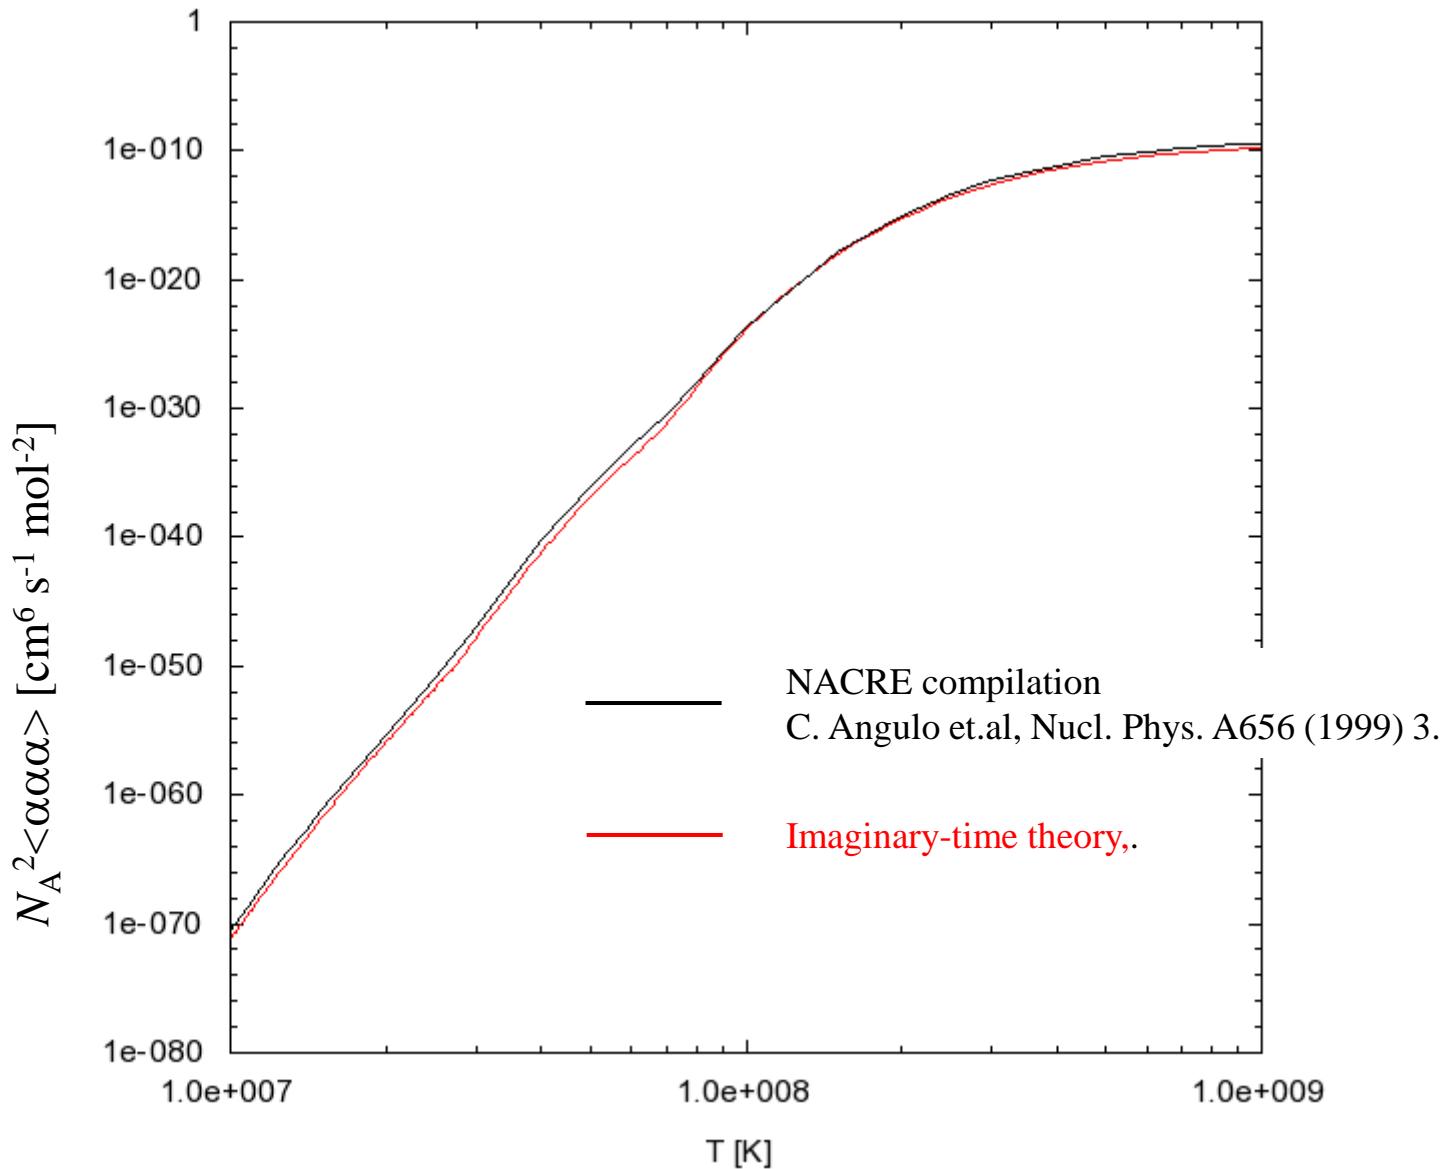

Coordinates

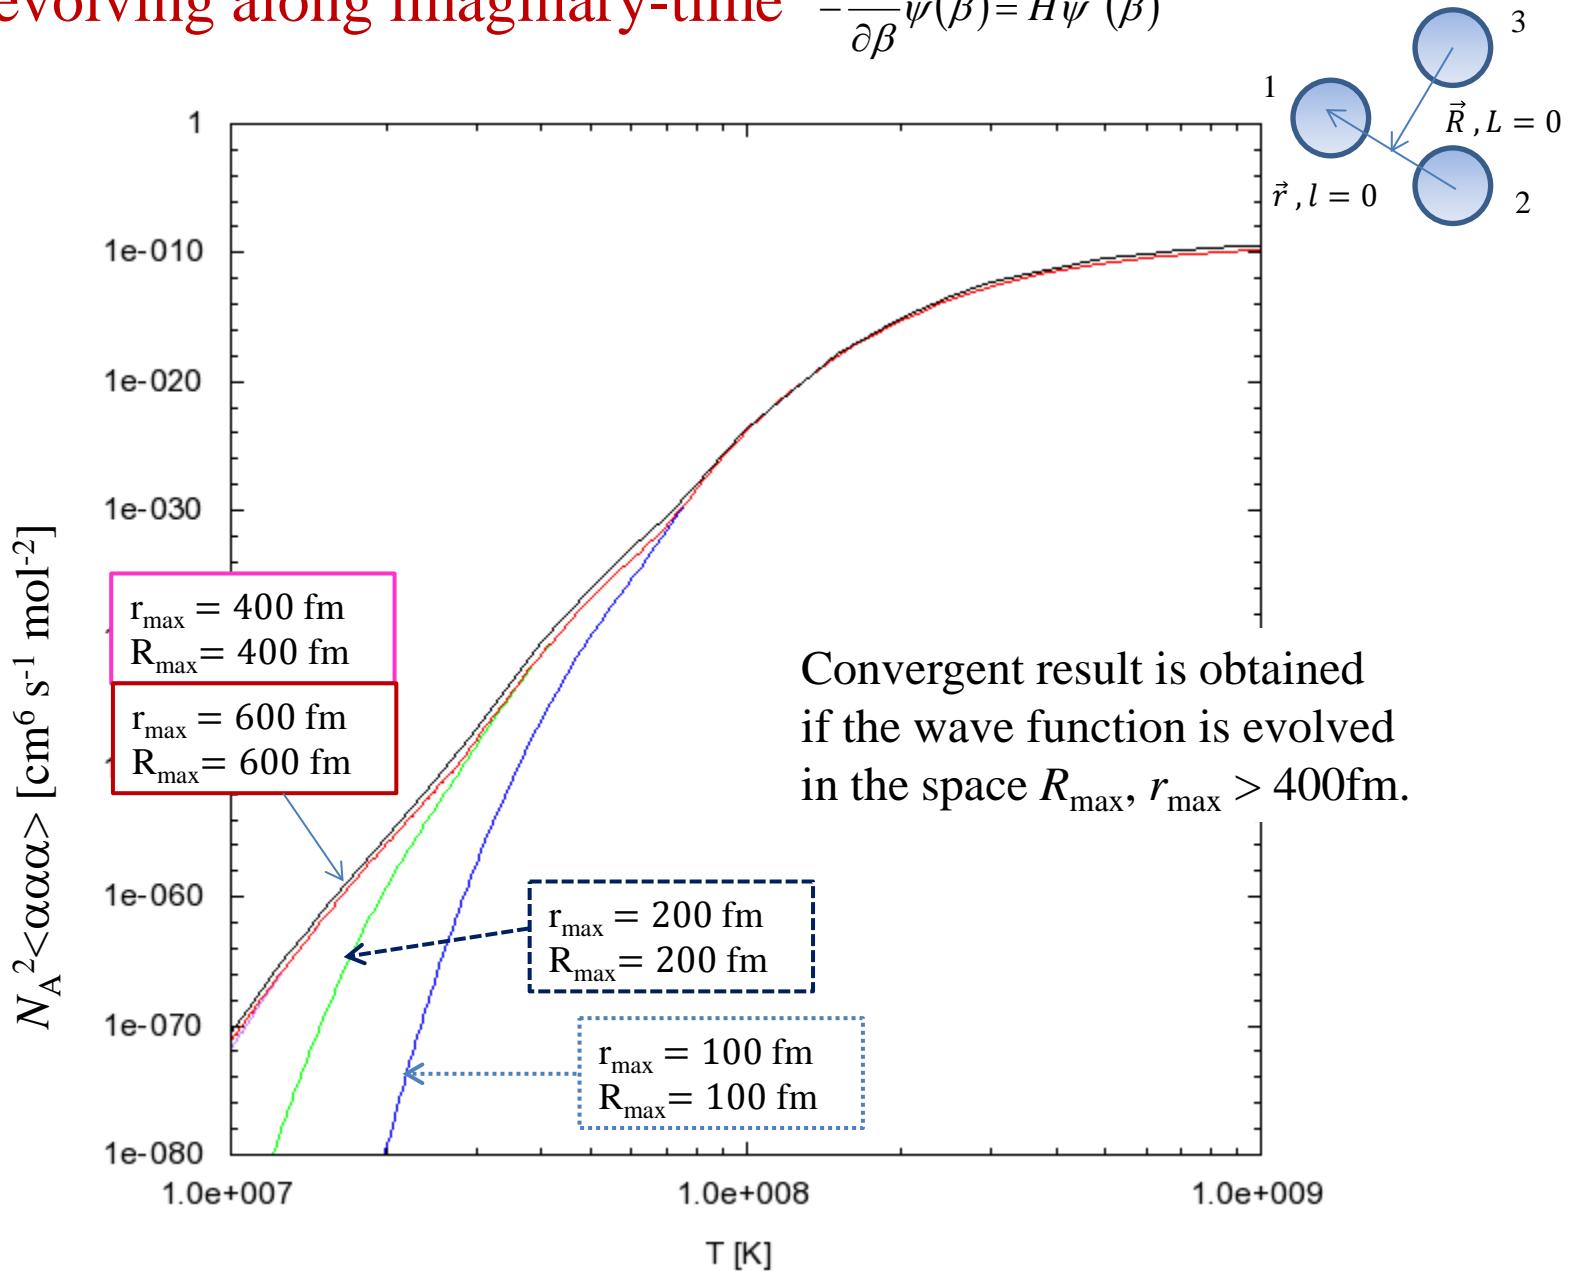

$$\psi(\vec{r}, \vec{R}, \beta) = \frac{u_{l=L=0}(r, R, \beta)}{rR} [Y_{l=0}(\hat{r}) Y_{L=0}(\hat{R})]_{J=0}$$

Jacobi coordinate, $l=L=0$ only (as in CDCC)
 Uniform grid for R and r

Triple-alpha reaction rate by the imaginary-time theory almost coincides with empirical NACRE rate.

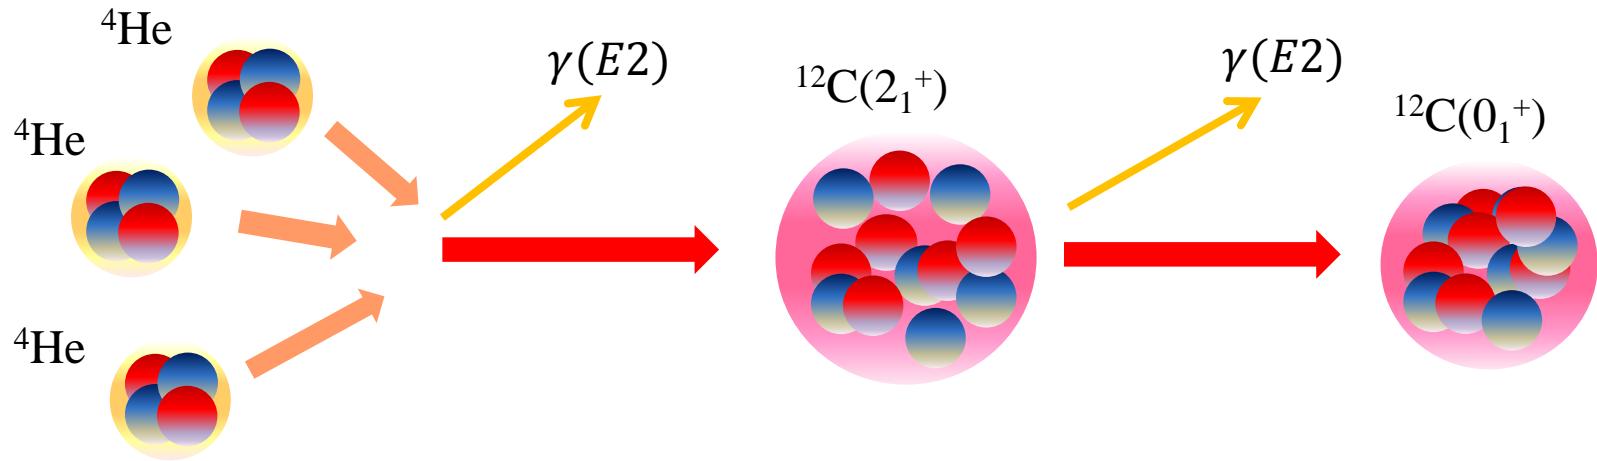

Convergence with respect to spatial size (R_{\max} and r_{\max}) in evolving along imaginary-time $-\frac{\partial}{\partial \beta} \psi(\beta) = H\psi(\beta)$

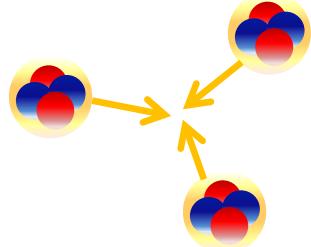

Dominant ^{12}C synthesis process depends on temperature

Total angular momentum 0

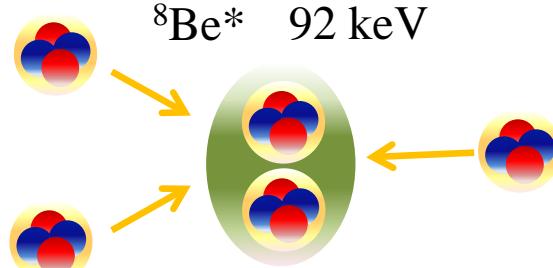

Low Temperature

Direct 3-alpha collision

↔

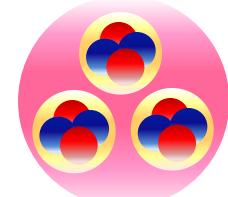

Binary collision
(^8Be resonance)

High Temperature

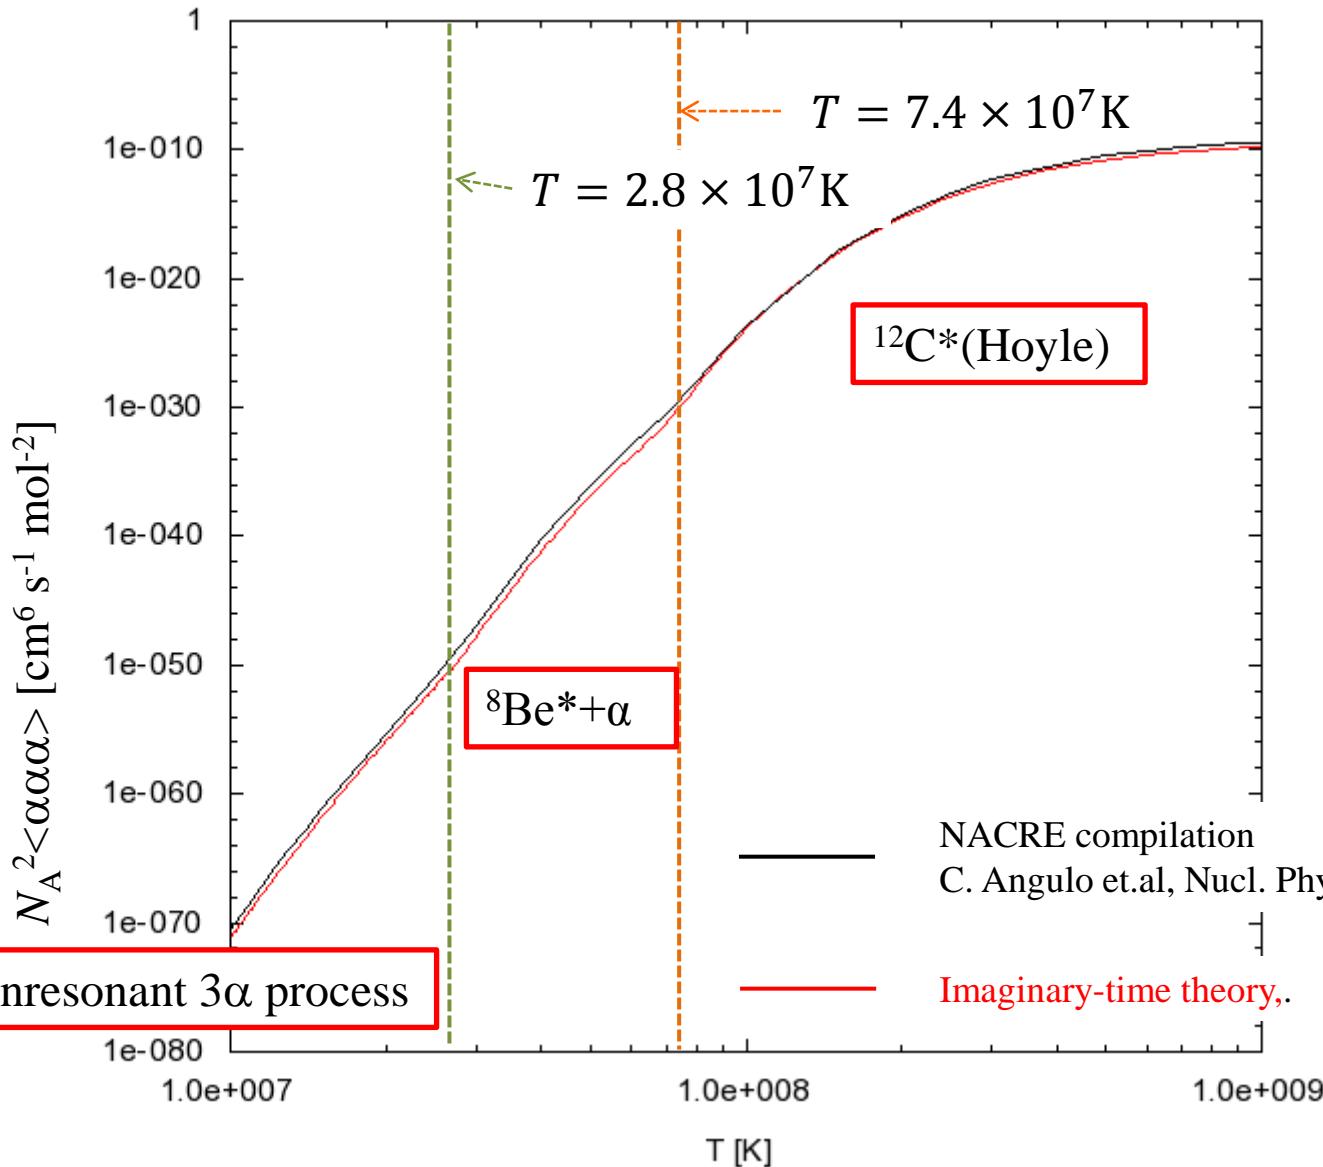

By way of Holy state
(^{12}C resonance)

$^{12}\text{C}^*(0_2^+) \quad 379 \text{ keV}$

Changes of reaction mechanisms at two temperatures in the empirical theory

K. Nomoto, Astrophys. J. 253, 798 (1982)

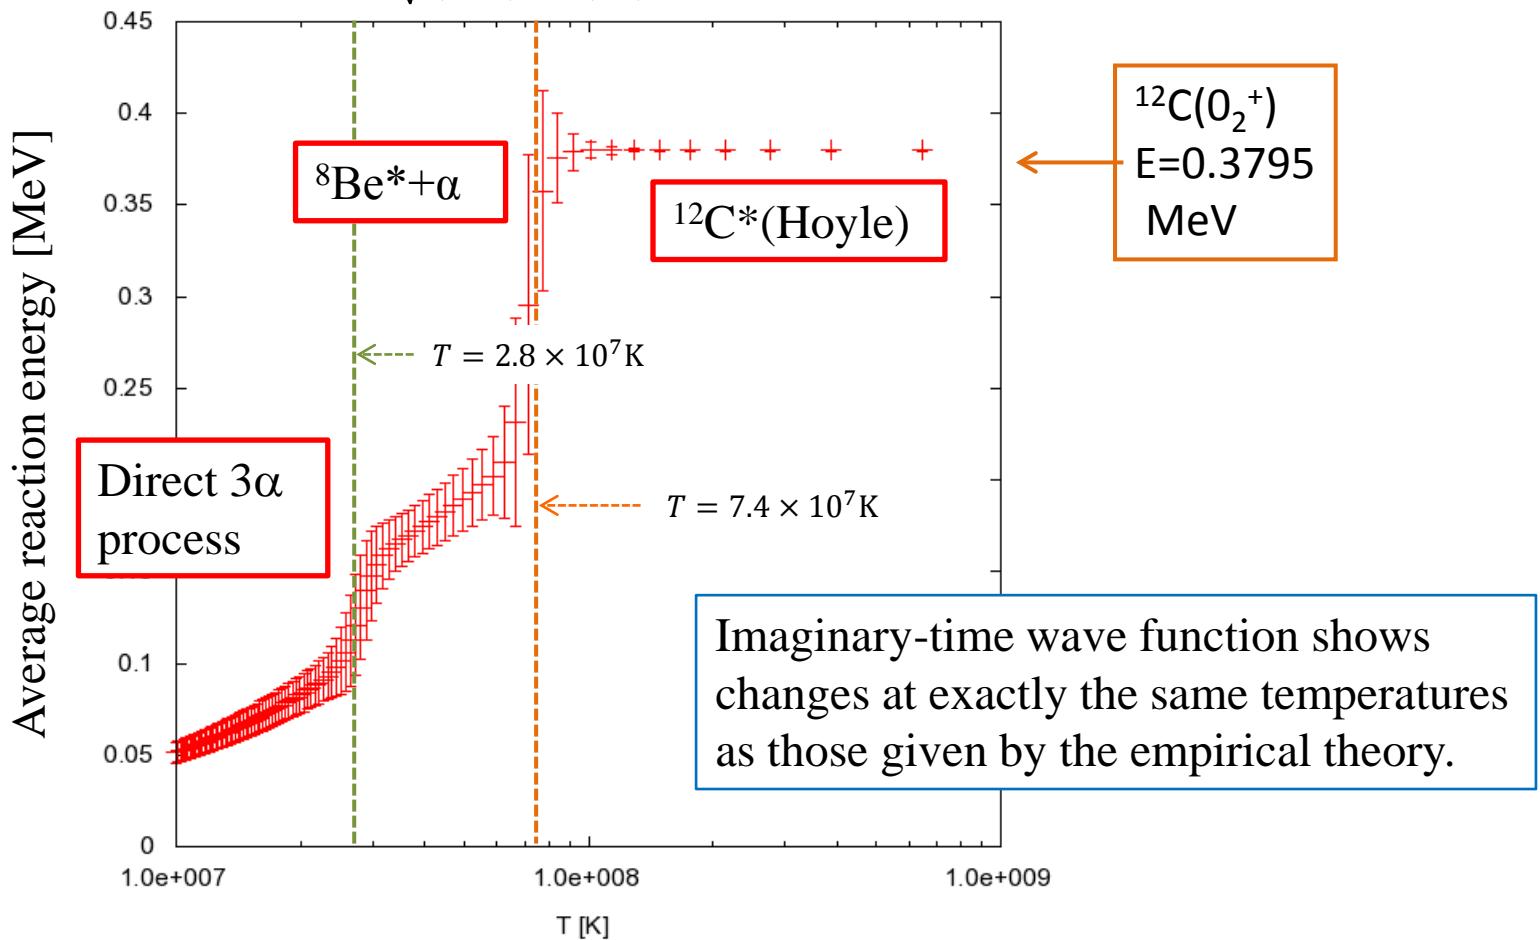

Average and variance of reaction energies as a function of temperature

$$\langle H \rangle \equiv \langle \Psi(\beta/2) | \hat{H} | \psi(\beta/2) \rangle$$

$$\langle H^2 \rangle \equiv \langle \Psi(\beta/2) | \hat{H}^2 | \psi(\beta/2) \rangle$$

$$\Delta H \equiv \sqrt{\langle H^2 \rangle - \langle H \rangle^2}$$

Though empirical and imaginary-time theories look very different,
calculated rate is almost the same.

Nomoto 1985, NACRE 1999:
Sequential 2-body process

$$\langle \alpha\alpha\alpha \rangle = 3 \int_0^\infty \frac{\hbar}{\Gamma_\alpha(\text{Be}, E_{\alpha\alpha})} \frac{d\langle \alpha\alpha \rangle(E_{\alpha\alpha})}{dE_{\alpha\alpha}} \langle \alpha\text{Be}(E_{\alpha\alpha}) \rangle dE_{\alpha\alpha}$$

Imaginary-time theory

$$\langle \alpha\alpha\alpha \rangle \propto \langle \phi_f | M_{\lambda\mu} e^{-\beta\hat{H}} \left(\frac{\hat{H} + |E_f|}{\hbar c} \right)^{2\lambda+1} \hat{P} M_{\lambda\mu}^+ | \phi_f \rangle$$

We next examine the relation analytically using R-matrix theory.

Derive the empirical formula in the imaginary-time theory

Two basic assumptions for microscopic 3-body Hamiltonian

1. The Hamiltonian is separable, into $\alpha\text{-}\alpha$ and $\alpha\text{-}{}^8\text{Be}$ parts

$$H = h_{\alpha\alpha} + h_{\alpha{}^8\text{Be}}$$

2. Hoyle state is described by a product of $\alpha\text{-}\alpha$ and $\alpha\text{-}{}^8\text{Be}$ resonant wave functions.

$$\Phi_H \approx \phi_{\alpha\alpha}^{\text{res.}}(\vec{r}) \phi_{\alpha\text{Be}}^{\text{res.}}(\vec{R})$$

Approximate spectral representation of H using R-matrix theory

$$\begin{aligned} f(\hat{H}) \rightarrow & |\phi_H\rangle\langle\phi_H| \int dE_{\alpha\alpha} \frac{1}{2\pi} \frac{\Gamma_r({}^8\text{Be}; E_{\alpha\alpha})}{(E_r({}^8\text{Be}) + \Delta_r(E_{\alpha\alpha}) - E_{\alpha\alpha})^2 + \Gamma_r(E_{\alpha\alpha})/4} \\ & \times \int dE_{\alpha{}^8\text{Be}} \frac{1}{2\pi} \frac{\Gamma_r({}^{12}\text{C}; E_{\alpha{}^8\text{Be}})}{(E_r({}^{12}\text{C}) + \Delta_r(E_{\alpha{}^8\text{Be}}) - E_{\alpha{}^8\text{Be}})^2 + \Gamma_r(E_{\alpha{}^8\text{Be}})/4} \\ & \times f(E_{\alpha\alpha} + E_{\alpha{}^8\text{Be}}) \end{aligned}$$

Put it in the rate expression of the imaginary-time theory

$$\langle\alpha\alpha\alpha\rangle \propto \langle\phi_f | M_{\lambda\mu} e^{-\beta\hat{H}} \left(\frac{\hat{H} - E_f}{\hbar c} \right)^{2\lambda+1} \hat{P} M_{\lambda\mu}^+ | \phi_f \rangle$$

Triple-alpha reaction rate derived from imaginary-time theory

$$\begin{aligned}
 \langle\alpha\alpha\alpha\rangle &= 6 \cdot 3^{\frac{3}{2}} \left(\frac{2\pi\hbar^2}{M_\alpha kT} \right)^3 \\
 &\times \int dE_{\alpha\alpha} \frac{1}{2\pi} \frac{\Gamma_\alpha(^8\text{Be}; E_{\alpha\alpha})}{(E_r(^8\text{Be}) - E_{\alpha\alpha})^2 + \Gamma_\alpha(E_{\alpha\alpha})/4} \\
 &\times \int dE_{\alpha^8\text{Be}} \frac{1}{2\pi} \frac{\Gamma_\alpha(^{12}\text{C}; E_{\alpha^8\text{Be}})}{(E_r(^{12}\text{C}) - E_{\alpha^8\text{Be}})^2 + \Gamma_\alpha(E_{\alpha^8\text{Be}})/4} \\
 &\times \exp \left[-\frac{E_{\alpha\alpha} + E_{\alpha^8\text{Be}}}{kT} \right] \cdot \Gamma_\gamma(^{12}\text{C}) \left(\frac{E_{\alpha\alpha} + E_{\alpha^8\text{Be}} - E(^{12}\text{C}; 2^+)}{E(^{12}\text{C}; 0_2^+) - E(^{12}\text{C}; 2^+)} \right)^{2\lambda+1}
 \end{aligned}$$

We ignore energy shift $\Delta(E)$

This expression mostly coincides with that of NACRE

$$\langle\alpha\alpha\alpha\rangle = 3 \int_0^\infty \frac{\hbar}{\Gamma_\alpha(\text{Be}, E_{\alpha\alpha})} \frac{d\langle\alpha\alpha\rangle(E_{\alpha\alpha})}{dE_{\alpha\alpha}} \langle\alpha\text{Be}(E_{\alpha\alpha})\rangle dE_{\alpha\alpha}$$

There are a few minor differences.

$$\frac{\Gamma_\alpha(^{12}\text{C}; E_{\alpha^8\text{Be}})}{(E_r(^{12}\text{C}) - E_{\alpha^8\text{Be}})^2 + \Gamma_\alpha(E_{\alpha^8\text{Be}})/4} \rightarrow \frac{\Gamma_\alpha(^{12}\text{C}; E_{\alpha^8\text{Be}})}{(E_r(^{12}\text{C}) + E_r(^8\text{Be}) - E_{\alpha^8\text{Be}} - E_{\alpha\alpha})^2 + \Gamma_\alpha(E_{\alpha^8\text{Be}})/4}$$

Imaginary-time theory

NACRE

(Not symmetric wrt $\alpha-\alpha$ and $\alpha-{}^8\text{Be}$)

Why different theories provide so different reaction rates ?

$$\langle \alpha\alpha\alpha \rangle_{\text{CDCC}} \gg \langle \alpha\alpha\alpha \rangle_{\text{Imaginary-Time}} \approx \langle \alpha\alpha\alpha \rangle_{\text{NACRE}}$$

10²⁶ order of magnitude difference at 10⁷ K

To clarify the origin of theoretical controversy,
we use coupled-channel expansion in the imaginary-time formalism

We first solve $\alpha-\alpha$ 2-body eigenvalue problem.

$$h_{\alpha\alpha} w_n(r) = \varepsilon_n w_n(r)$$

$$\int_0^{r_{\max}} dr w_m(r) w_n(r) = \delta_{mn}$$

We then expand 3-body wave function with this basis

$$u(r, R, \beta) = \sum_n \chi_n(R, \beta) w_n(r)$$

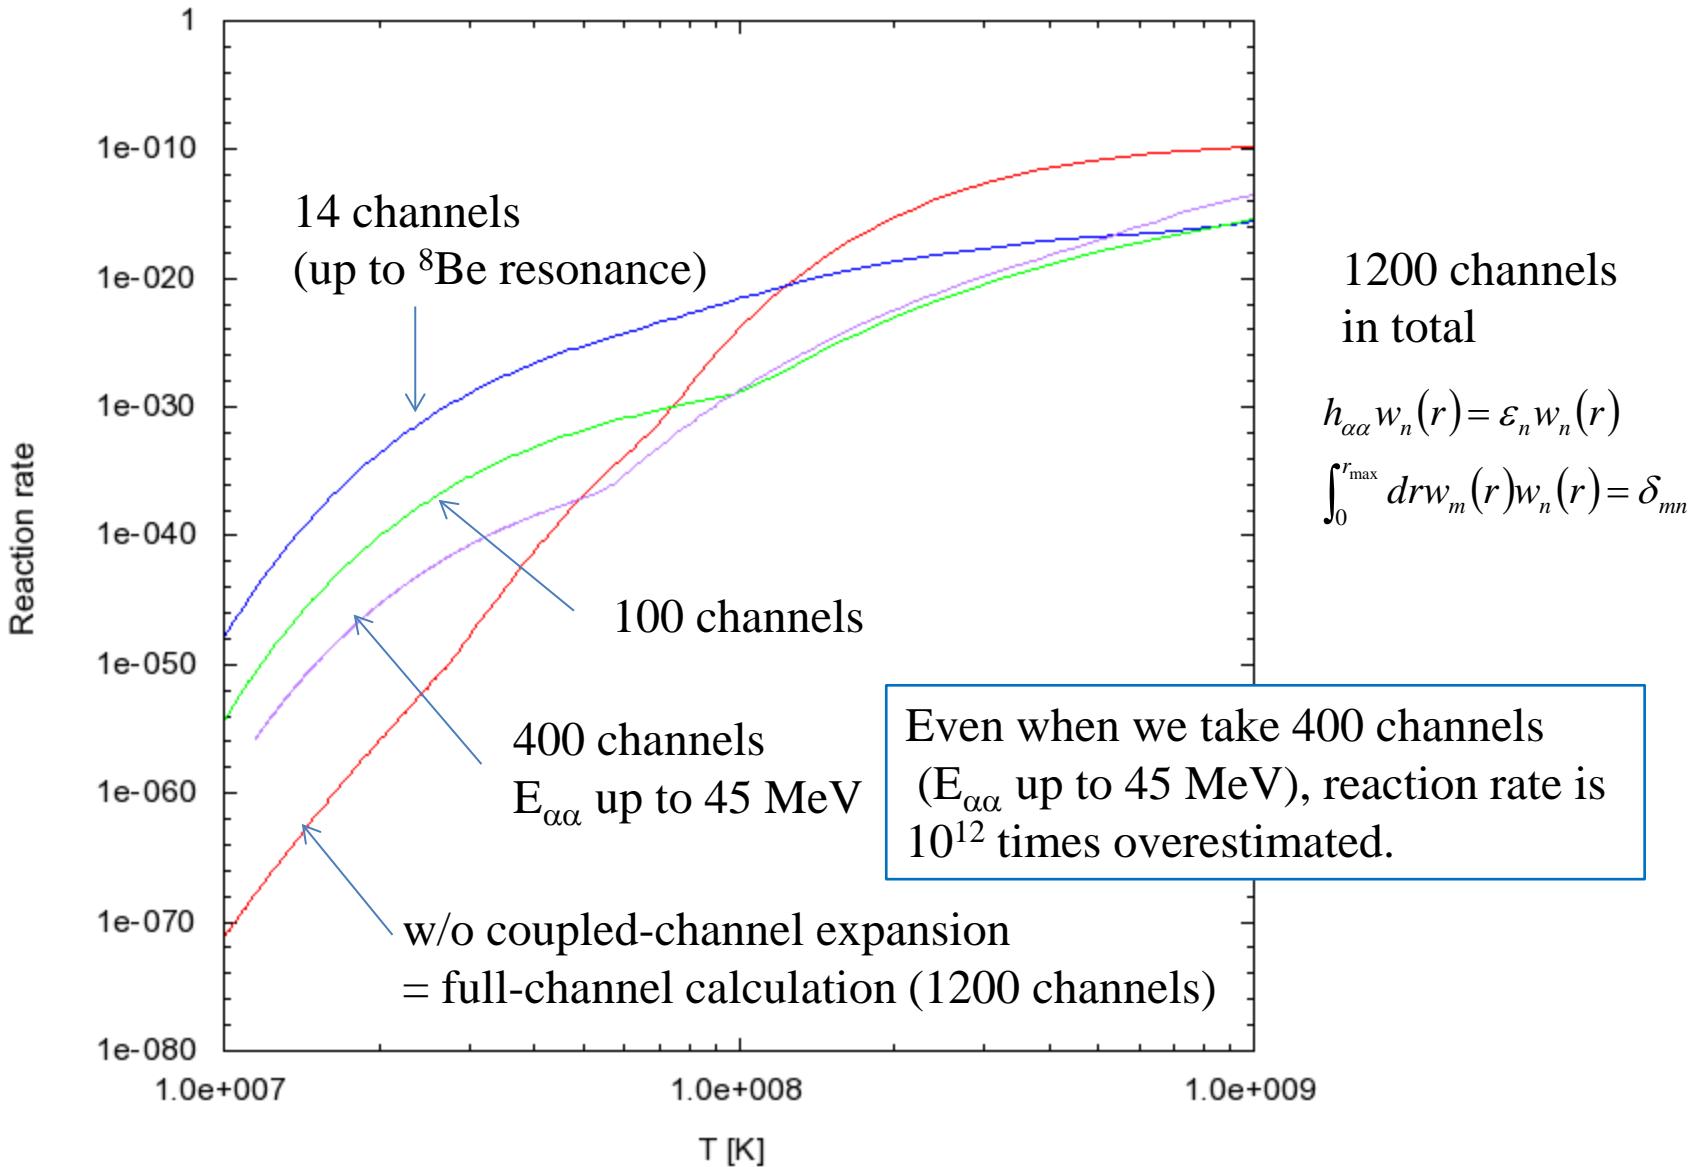

We then solve “coupled-channel imaginary-time equation”

$$-\frac{\partial}{\partial \beta} \chi_n(R, \beta) = \left[-\frac{\hbar^2}{2M} \frac{\partial^2}{\partial R^2} + \varepsilon_n \right] \chi_n(R, \beta) + \sum_{n'} V_{nn'}(R) \chi_{n'}(R, \beta)$$

Using complete set (all eigenfunction), $\{w_n(r)\}$, results should not change.
However, if we make a truncation, the result may be different.

Convergence of expansion is extremely slow !

Warning the use of coupled-channel method for quantum tunneling

Conclusion

Imaginary-time theory for radiative capture process

- It does not require any scattering solution to calculate reaction rate

Triple-alpha reaction rate using the imaginary-time theory

- We can calculate a convergent reaction rate.
- The calculated reaction rate mostly coincides with that of NACRE
- Changes of reaction mechanisms occur at the same temperature of those of NACRE.

Analytical relation between the imaginary-time theory and the empirical formula

- Using R-matrix theory and assuming separable approximation,
the imaginary-time theory gives almost the same formula as that of NACRE.

Origin of theoretical controversy

- We find an extremely slow convergence if we make a coupled-channels expansion.
